Lowland, Tennessee 37778

Subject: Powerhouse And Water Treatment Structures Asbestos Survey Report
Former Liberty Fibers Site; Lowland, Tennessee
A.C.T. Services Proposal No. 08.17.001

Dear Mr. Williams,

A.C.T. Services, LLC. (ACT) has completed the site investigation and analysis of suspect asbestos-containing building materials collected from the Powerhouse and Water Treatment Plant structures within the Former Liberty Fibers site located in Lowland, Tennessee as per your acceptance of our proposal number 08-025 dated May 9, 2008.

The limited survey was performed to determine the presence of asbestos-containing building materials that may be affected by the planned demolition of both structures. The suspect asbestos-containing building materials sampled include thermal pipe insulation, thermal boiler insulation, gasket materials, resilient floor covering, drywall construction, acoustical ceiling tile, roofing membranes, window glazing and various other miscellaneous building materials.

The attached report presents descriptions and results of the material sampling procedures and laboratory analysis methodology. Relevant general project information is also provided, followed by our findings and recommendations. Sample analysis results are provided in the enclosed Appendices. Representative samples of suspect asbestos-containing materials that may be affected by the planned demolition were collected in general accordance with U.S. Environmental Protection Agency (EPA) guidelines.

We appreciate this opportunity to provide environmental consulting services to A&E Salvage, Inc. If you have any questions or require further information, please do not hesitate to call.

Sincerely,

A.C.T. Services, LLC.

A handwritten signature in black ink, appearing to read "MJ Roberts", written over a horizontal line.

Michael J. Roberts

Appendix E – BULK SAMPLE CHAIN OF CUSTODY

Appendix F – ASBESTOS CERTIFICATION

1.0 EXECUTIVE SUMMARY

The limited survey for asbestos-containing building materials (ACBM's) within the Power House and Water Treatment areas of the Liberty Fibers site located in Lowland, Tennessee, included visual observations, material sampling and laboratory analysis of building materials suspected of containing regulated asbestiform minerals.

The initial fieldwork and sample collection was completed during our weeklong site visit performed between June 30, 2008 through July 3, 2008 by Mr. Michael Roberts (Asbestos Inspector Certification No. 10566). The ACBM investigation was generally destructive by nature. Areas enclosed between concrete and block walls or otherwise structurally inaccessible were not observed or sampled. Limited attempts were made to disassemble equipment or demolish finishes to access suspect ACBM's.

A total of three hundred eighteen (318) suspect asbestos-containing building material samples were obtained during ACT's site visit. The building material samples were collected from various locations within the powerhouse structure, exterior pipe rack system and vessels, water treatment plant, break room and locker room structure, maintenance storage building and supervisor's office structure scheduled for demolition.

The building materials sampled include thermal pipe insulation, thermal boiler insulation, thermal vessel insulation, gasket materials, resilient floor covering, drywall construction, acoustical ceiling tile, roofing membranes, window glazing and various other miscellaneous building materials that may be affected by the demolition activities. The US Environmental Protection Agency (EPA) and Tennessee Department of Environment and Conservation (TDEC) consider asbestos-containing building materials, which are or may become friable during the course of demolition activities, regulated asbestos-containing materials (RACM).

Friable asbestos material means any material containing more than 1 percent asbestos as determined using the method specified in appendix E, subpart E, 40 CFR part 763, section 1, Polarized Light Microscopy, that, when dry, can be crumbled, pulverized, or reduced to powder by hand pressure. If the asbestos content is less than 10 percent as determined by a method other than point counting by polarized light microscopy (PLM), verify the asbestos content by point counting using PLM.

Regulated asbestos-containing material (RACM) means (a) Friable asbestos material, (b) Category I non-friable ACM that has become friable, (c) Category I non-friable ACM that will be or has been subjected to sanding, grinding, cutting, or abrading, or (d) Category II non-friable ACM that has a high probability of becoming or has become crumbled, pulverized, or reduced to powder by the forces expected to act on the material in the course of demolition or renovation operations regulated by this subpart.

Category I non-friable asbestos-containing material (ACM) means asbestos-containing packings, gaskets, resilient floor covering, and asphalt roofing products containing more than 1 percent asbestos as determined using the method specified in appendix E, subpart E, 40 CFR part 763, section 1, Polarized Light Microscopy. Category II non-friable ACM means any material, excluding Category I non-friable ACM, containing more than 1 percent asbestos as determined using the methods specified in Appendix E, subpart E, 40 CFR part 763, section 1, Polarized Light Microscopy that, when dry, cannot be crumbled, pulverized, or reduced to powder by hand pressure.

Of the suspect asbestos-containing building materials sampled, various thermal pipe insulation, thermal boiler insulation, thermal vessel insulation, gasket materials, resilient floor covering, drywall construction, roofing membranes, vapor barrier mastic wrap, and various other miscellaneous building materials were found to contain greater than one percent (>1%) regulated asbestiform minerals using polarized light microscopy coupled with dispersion staining (PLM/DS) in accordance with EPA 600/R-93/116 Method. Due to the large number of homogeneous asbestos-containing building materials identified at the facility we have compiled a summary list of these materials and their general locations in Section 3.2 of this report. A complete copy of the laboratory analysis is included in the appendices.

According to Mr. Randle Harrison of TDEC, if the planned demolition is performed, the friable asbestos-containing thermal system pipe insulation, boiler insulation, equipment insulation, vessel insulation, duct insulation, access door gaskets and drywall construction materials must be removed by a qualified asbestos abatement contractor prior to the demolition activity. Category I non-friable acm's such as resilient flooring, asphalt roofing, mastics, gaskets and packings in good condition may remain in place during demolition and are not subject to National Emission Standard for Hazardous Air Pollutants (NESHAP) regulations 40 CFR Part 61 Subpart M National Emission Standard For Asbestos waste disposal requirements. Compaction for waste reduction of Category I and/or Category II non-friable asbestos-containing debris by demolition equipment (e.g. track loaders, excavators, etc.) is considered rendering these materials friable and RACM waste disposal regulations will be required.

TDEC's interpretation
It is EPA's interpretation that waste resulting from ^{regulated} slicing and other methods that do not cut, grind, sand or abrade Category I non-friable asbestos-containing roofing material is not subject to the NESHAP and can be disposed of as non-asbestos waste. EPA further construes the NESHAP to provide that if Category II roofing material (such as asbestos cement shingles) is removed and disposed of without crumbling, pulverizing, or reducing it to powder, the waste from the removal is not subject to the NESHAP waste disposal requirements. EPA also interprets the NESHAP to be inapplicable to waste resulting from roof removal operations that do not meet or exceed the coverage thresholds described in the regulation. Of course, other State, local, or Federal regulations may apply. *it is in good condition and not co-mingled*

All asbestos abatement work must comply with NEHSAP and Occupational Safety and Health Administration regulations stipulated in the Code of Federal Regulations (CFR) 29 1926.1101 titled "Asbestos". Other regulations may also apply and are cross-referenced in both NESHAP and OSHA standards, which are presented to promote compliance with the cited regulations. *this is already removed in place*

2.0 PROJECT INFORMATION

The Liberty Fibers Site, located in Lowland, Tennessee, has undergone various demolition activities by A&E Salvage in conjunction with a proposing site redevelopment. The Power House area and Water Treatment Plant were scheduled for demolition as part of the redevelopment program. A&E Salvage had performed some asbestos removal and demolition activities on the Power House prior to ACT's initial site visit. *① bldg's ② piles*

At the time of ACT's initial site visit, boiler units number 5 thru 9, a portion of the turbine room and most of the compressor room had been demolished. The Water Treatment Plant area remained intact with no asbestos removal or demolition activities performed at that time. Construction material debris fields were observed surrounding the demolished Power House structures. It was our understanding that a stop work order was issued to A&E Salvage by the US EPA Region 4. *depends on what is in the pile*

The remaining Power House structure contains four (4) Babcock & Wilcox coal fueled steam power boilers and associated air heaters, coal feed bins, coal pulverizers, de-aerator tank, hot well tanks, steam lines, condensate lines, water feed lines and precipitator. The Water Treatment Plant consists of a supervisor's office structure, maintenance storage building, break room and locker room building and water filtration equipment building. Several exterior pipe racks and large hot water tanks were also located within the designated survey area. Photographs and diagrams are included in the appendices for further information.

Upon our initial site visit we observed various homogeneous building materials, including but not limited to, thermal pipe insulation, thermal boiler insulation, thermal vessel insulation, gasket materials, resilient floor covering, drywall construction, acoustical ceiling tile, roofing membranes, window glazing and various other miscellaneous building materials which were suspected to contain regulated asbestiform minerals.

The scope of investigative services addressed in this report are limited to the building materials within the Power House and Water Treatment area scheduled for demolition. The assessment of other potential sources of environmental hazards was not included in this scope of work. A pre-existing asbestos survey report was not available at the time of our site investigation.

3.0 ASBESTOS PROCEDURES AND RESULTS

The services provided in this phase of the work included a visual survey of the designated Power House and Water Treatment area scheduled for demolition, suspect building material sampling and laboratory analysis for asbestiform minerals. The following paragraphs discuss the general procedures employed for each of these tasks.

3.1 Visual Survey

The visual survey for suspected asbestos-containing materials included observation of thermal pipe insulation, thermal boiler insulation, thermal vessel insulation, gasket materials, resilient floor covering, drywall construction, acoustical ceiling tile, roofing membranes, window glazing and various other miscellaneous building materials. The primary purpose of the visual survey was to locate and identify friable and non-friable building materials suspected of containing asbestos which may be disturbed during the planned demolition activities. "Friable materials" are those that can be crumbled, pulverized or reduced to powder by hand pressure, releasing fibers into the air.

The next phase of the survey involved identification of suspect materials associated with the proposed demolition project and sample collection. Suspect materials observed and sampled included thermal pipe insulation, thermal boiler insulation, thermal vessel insulation, gasket materials, resilient floor covering, drywall construction, acoustical ceiling tile, roofing membranes, window glazing and various other miscellaneous building materials.

3.2 Material Sample Analysis and Summary of Results

A total of three hundred eighteen (318) material samples were collected and delivered to our accredited laboratory for visual observation and analysis. The samples were analyzed using Polarized Light Microscopy (PLM) coupled with Dispersion Staining as detailed in the United States Environmental Protection Agency's (EPA) "Method for the Determination of Asbestos in Bulk Building Materials" (EPA-600/R-93/116, July 1993).

A complete list describing the materials sampled, their general location, and their laboratory results is presented in the Appendix. The EPA considers a material to be asbestos containing only if it contains greater than one percent (>1%) asbestos as appropriately determined by PLM, which may include point count analysis. The following is an abbreviated overview of general building materials containing regulated asbestiform minerals within the structures specified for investigation.

General Locations	ACBM Description	Asbestos Type & Content

Precipitator Area Condensate Tank	Condensate Tank Vapor Barrier	25-30% Chrysotile
Precipitator Area Condensate Tank	Vessel Vapor Barrier	25-30% Chrysotile

At the request of the A & E Salvage, ACT Services also collected additional samples from two areas of concern. The first area included a locked maintenance or storage room located at the north end of the boiler room ground level, which appeared to have stored suspect asbestos-containing materials piled approximately five (5) feet high. These materials were observed to be dry and not contained in any type of leak-tight impermeable containers.

The second area of concern was located along a surveyors line that appeared to have construction material debris graded to beyond the surveyors line. The line of debris extended from the Power House cross roads located west of the Power House and railroad tracks extending approximately 120 feet in a westerly direction and then turning north approximately 100 feet. The graded area encompassed a large concrete tank of unknown contents.

The results of this survey area as follows:

<i>General Locations</i>	<i>ACBM Description</i>	<i>Asbestos Type & Content</i>
Boiler Room Locked Room Debris:		
Boiler Room Ground Floor North End Locked Room	TSI Debris - Gray	25% Chrysotile
Boiler Room Ground Floor North End Locked Room	TSI Debris - Brown	40% Chrysotile
Debris Field West of Power House and South of Concrete Tank:		
South Surveyors Line – 4' West of Railroad Tracks	TSI Vapor Barrier Debris	8% Chrysotile
South Surveyors Line – 15' West of Railroad Tracks	Black Roof Debris	25% Chrysotile
South Surveyors Line – 75' West of Railroad Tracks	Silver/Black Mastic Debris	2% Chrysotile
South Surveyors Line – 85' West of Railroad Tracks	Silver/Black Mastic Debris	2% Chrysotile
South Surveyors Line – 10' West of Fire Hydrant	Black Roof Debris	10% Chrysotile
South Surveyors Line – 30' West of Fire Hydrant	Fibrous Roll Insulation	10% Chrysotile
West Surveyors Line – 20' North of South Boundary Road Tracks	Fibrous Roll Insulation	10% Chrysotile
West Surveyors Line – 70' North of South Boundary Road Tracks	Fibrous Roll Insulation	30% Chrysotile

3.3 Material Assessment

The EPA's National Emission Standard for Hazardous Air Pollutants (NESHAP) regulations (40 CFR 61 (M)) require that regulated asbestos-containing materials (RACM) be properly removed prior to any demolition or renovation activity, which may disturb them. The EPA NESHAP regulations define RACM as:

- (a) Friable ACM;
- (b) Category I non-friable ACM that has become friable;
- (c) Category I non-friable ACM that will be or has been subject to sanding, grinding, cutting or abrading, or;
- (d) Category II non-friable ACM that has a high probability of becoming, or has become, crumbled, pulverized, or reduced to powder by the forces expected to act on the material in the course of demolition or renovation operations.

Building materials that contain less than one (1) percent asbestos are not currently subject to EPA regulations. However, it should be noted that the disturbance of these materials may be subject to regulations issued by the U.S. Occupational Safety and Health Administration (OSHA).

Such a disturbance may elevate the concentration of airborne fibers above the permissible exposure limit (PEL) of 0.1 fibers per cubic centimeter (f/cc) of air, measured as an eight (8) hour time weighted average (TWA), or the 30-minute short term excursion limit (STEL) of 1.0 f/cc. Recent revisions to the OSHA regulations require that all surfacing materials, thermal system insulation materials, and resilient flooring installed "no later than 1980" be considered as presumed asbestos-containing materials (PACM) and treated accordingly.

Furthermore, OSHA has implemented the final rule for occupational exposure to asbestos to include regular building maintenance operations and custodial activities that may disturb identified or presumed asbestos-containing materials. In order to rebut the designation of installed materials as PACM, OSHA requires the sampling of suspect material be performed in accordance with 40 CFR 763 (E) issued by the EPA under the Asbestos Hazard Emergency Response Act of 1986 (AHERA). The AHERA regulations establish asbestos identification and management requirements for schools, grades K through 12. The recent OSHA revisions also include specific notification and engineering control procedures.

4.0 ASBESTOS EXPOSURE ASSESSMENT AND RECOMMENDATIONS

Asbestos is an airborne hazard. An assessment of potential exposure to harmful asbestos fibers from asbestos-containing materials should evaluate the material's potential to release fibers into the air. Fiber release may occur spontaneously due to the normal aging and subsequent deterioration of the materials. Fiber release may also occur suddenly due to disturbance of the materials by maintenance, renovations, demolition, accidents, excessive vibrations, or water damage. As a part of the survey, a visual assessment was performed in order to ascertain the potential for asbestos fiber release from the identified building materials.

The assessment focused upon specific criteria which include asbestos content (percentage and type); friability; evidence of deterioration, physical damage or water damage; proximity to an air stream; and accessibility. The effects of potential demolition activities were considered separately for each affected material found to contain asbestos. Such an exposure assessment is qualitative in nature. The surveyor, based upon facility characteristics, prior experience, and an understanding of abatement alternatives and known demolition plans evaluates these criteria qualitatively. This method of evaluation is outlined in the EPA's "Guidance for Controlling Asbestos-Containing Materials in Buildings" (EPA 560/5-85-024).

The results of the evaluations are reported in the following relative terms describing the potential for asbestos fiber release.

- Materials that are in good physical condition and exhibit little chance for disturbance are considered to have a "low" potential for fiber release.
- Materials that are in poor condition with some deterioration or damage, or exhibit some risk for disturbance present a "medium" potential for fiber emission.
- Materials that are in generally poor condition and exhibit the affinity for further deterioration, damage, or disturbance are considered to present a "high" potential to generate airborne fibers.
- Materials assessed as an "imminent hazard" are typically damaged, openly exposed, likely to be disturbed and display a very high possibility of releasing fibers into the air.

From the exposure assessments, recommendations for control alternatives are determined and prioritized. Understanding that this survey has been performed for demolition purposes and for the development of asbestos abatement work procedure design, ACT Services has utilized the NESHAP evaluation criteria and OSHA referenced regulations for this assessment.

The following assessments have been determined based on the understanding that this development site will be demolished as planned. However, if construction plans allow for the asbestos-containing materials to remain in place, then we recommend that these materials be included in an asbestos operations and maintenance (O&M) program until such time as they are properly removed. Long range planning should take into consideration the complete removal of all asbestos-containing materials by a qualified asbestos abatement contractor under properly controlled conditions.

4.1 Thermal System Pipe Insulation Material.

The asbestos-containing thermal system pipe insulation material, in place and in good condition, is considered as RACM by NESHAP definition, and must be removed prior to the planned demolition. The friable asbestos-containing thermal system pipe insulation material, in its present condition and location, pose a medium potential for airborne asbestos fiber exposure.

Removal operations, waste packaging and disposal of friable asbestos-containing thermal system insulation must be performed in accordance with NESHAP regulations that include notification, personnel training, no visible emissions and adequately wetting waste materials throughout the process. OSHA regulations consider asbestos-containing thermal system insulation removal for demolition as Class I removal activities and require the use of critical barriers or other isolation method which prevent the migration of airborne asbestos from a designated regulated area.

The removal of friable asbestos-containing thermal system insulation material should be performed by a qualified asbestos abatement contractor under properly controlled conditions in accordance with EPA, TDEC and OSHA removal and disposal regulations.

4.2 Thermal System Boiler Insulation Material.

The asbestos-containing thermal system boiler, mud drum, steam drum and dead air space insulation materials, in place and in good condition, is considered as RACM by NESHAP definition, and must be removed prior to the planned demolition. The friable asbestos-containing thermal system pipe insulation material, in its present condition and location under a metal jacket, pose a low potential for airborne asbestos fiber exposure.

Removal operations, waste packaging and disposal of friable asbestos-containing thermal system insulation must be performed in accordance with NESHAP regulations that include notification, personnel training, no visible emissions and adequately wetting waste materials throughout the process. OSHA regulations consider asbestos-containing thermal system boiler insulation removal for demolition as Class I removal activities and require the use of critical barriers or other isolation method which prevent the migration of airborne asbestos from a designated regulated area.

The removal of friable asbestos-containing thermal system insulation material should be performed by a qualified asbestos abatement contractor under properly controlled conditions in accordance with EPA, TDEC and OSHA removal and disposal regulations.

4.3 Thermal System Equipment & Duct Insulation Material.

The asbestos-containing canvas wrapped thermal system fan housing, air heater, pulverizer and duct insulation materials, in place and in good condition, is considered as RACM by NESHAP definition, and must be removed prior to the planned demolition. The friable asbestos-containing thermal system pipe insulation material, in its present condition and location, pose a medium potential for airborne asbestos fiber exposure.

Removal operations, waste packaging and disposal of friable asbestos-containing thermal system fan housing, air heater duct, pulverizer and duct insulation must be performed in accordance with NESHAP regulations that include notification, personnel training, no visible emissions and adequately wetting waste materials throughout the process. OSHA regulations consider asbestos-containing thermal fan housing, air heater duct, pulverizers and duct system insulation removal for demolition as Class I removal activities and require the use of critical barriers or other isolation method which prevent the migration of airborne asbestos from a designated regulated area.

The removal of friable asbestos-containing thermal system insulation material should be performed by a qualified asbestos abatement contractor under properly controlled conditions in accordance with EPA, TDEC and OSHA removal and disposal regulations.

4.4 Thermal System Vessel Insulation Material.

The asbestos-containing thermal system de-aerator tank, hot well tank, hot water tank, anthracite filter tank and condensate tank insulation materials, in place and in good condition, is considered as RACM by NESHAP definition, and must be removed prior to the planned demolition. The friable asbestos-containing thermal system vessel insulation material, in its present condition and location, pose a medium potential for airborne asbestos fiber exposure.

Removal operations, waste packaging and disposal of friable asbestos-containing thermal system de-aerator tank, hot well tank, hot water tank, anthracite filter tank and condensate tank insulation must be performed in accordance with NESHAP regulations that include notification, personnel training, no visible emissions and adequately wetting waste materials throughout the process. OSHA regulations consider asbestos-containing thermal de-aerator tank, hot well tank, hot water tank, anthracite filter tank and condensate tank insulation removal for demolition as Class I removal activities and require the use of critical barriers or other isolation method which prevent the migration of airborne asbestos from a designated regulated area.

The removal of friable asbestos-containing thermal system insulation material should be performed by a qualified asbestos abatement contractor under properly controlled conditions in accordance with EPA, TDEC and OSHA removal and disposal regulations.

4.5 Roofing Material.

The non-friable asbestos-containing roofing material, in place and in good condition, is considered a Category I non-friable ACM by NESHAP definition, and may remain in place during the planned demolition. The non-friable asbestos-containing roofing material, in its present condition and location, pose a low potential for airborne asbestos fiber exposure.

TDEC's interpretation of waste resulting from slicing and other methods that do not cut, grind, sand or abrade Category I non-friable asbestos-containing roofing material is not subject to the NESHAP rule and can be disposed of as non-asbestos waste. OSHA regulations consider asbestos-containing roofing material removal for demolition as Class II removal activities and

shall be removed in an intact state with wet removal methods to the extent feasible that prevent the migration of airborne asbestos from a designated regulated area.

The removal of non-friable asbestos-containing roofing material should be performed by a qualified asbestos abatement contractor under properly controlled conditions in accordance with EPA, TDEC and OSHA removal and disposal regulations.

4.6 Mechanical Gasket Material.

Several types of asbestos-containing mechanical gasket materials were identified during the survey. The gasket materials include non-friable preformed flange gasket material used to seal pipe and equipment flanges and also friable boiler equipment access panel woven gasket material used to seal inspection panels after maintenance and repair activities.

The non-friable asbestos-containing flange gasket material, in place and in good condition, is considered a Category I non-friable ACM by NESHAP definition, and may remain in place during the planned demolition. The non-friable Category I asbestos-containing flange gasket material, in its present condition and location, pose a low potential for airborne asbestos fiber exposure.

The friable asbestos-containing boiler equipment access panel woven gasket material, in place and in good condition, is considered as RACM by NESHAP definition, and must be removed prior to the planned demolition. The friable asbestos-containing boiler equipment access panel woven gasket material, in its present condition and location, pose a medium potential for airborne asbestos fiber exposure.

Removal operations, waste packaging and disposal of friable asbestos-containing boiler equipment access panel woven gasket material must be performed in accordance with NESHAP regulations that include notification, personnel training, no visible emissions and adequately wetting waste materials throughout the process. OSHA regulations consider asbestos-containing boiler equipment access panel woven gasket removal for demolition as Class II removal activities and shall be removed in an intact state with wet removal methods to the extent feasible that prevent the migration of airborne asbestos from a designated regulated area.

The removal of friable and non-friable asbestos-containing mechanical gasket material should be performed by a qualified asbestos abatement contractor under properly controlled conditions in accordance with EPA, TDEC and OSHA removal and disposal regulations.

4.7 Drywall Joint Compound Material.

The non-friable asbestos-containing drywall joint compound material, in place and in good condition, should be considered a RACM (ACM that will become delaminated and friable during demolition) and must be removed prior to the planned demolition operation. The non-friable asbestos-containing drywall joint compound material, in its present condition and location, pose a low potential for airborne asbestos fiber exposure.

Furthermore, OSHA does not accept composite material sampling of drywall construction. If the drywall joint compound material is found to contain greater than one percent (>1%) this material must be handled in accordance with OSHA 29 CFR 1926.1101 regulations. These regulations stipulate engineering controls and personnel protective equipment needed to reduce employee exposure.

The removal of non-friable asbestos-containing drywall joint compound material should be performed by a qualified asbestos abatement contractor under properly controlled conditions in accordance with EPA, TDEC and OSHA removal and disposal regulations.

4.8 Resilient Floor Tile Material.

The non-friable asbestos-containing resilient floor tile material, in place and in good condition, is considered a Category I non-regulated ACM by NESHAP definition, and may remain in place during the planned demolition. The non-friable asbestos-containing resilient floor covering material, in its present condition and location, pose a low potential for airborne asbestos fiber exposure.

TDEC's interpretation of waste resulting from normal demolition practices and other methods that do not cut, grind, sand or abrade Category I non-friable asbestos-containing resilient floor tile material is not subject to the NESHAP rule and can be disposed of as non-asbestos waste material. OSHA regulations consider asbestos-containing floor tile material removal for demolition as Class II removal activities and shall be removed in an intact state with wet removal methods to the extent feasible that prevent the migration of airborne asbestos from a designated regulated area.

The removal of non-friable asbestos-containing floor tile material should be performed by a qualified asbestos abatement contractor under properly controlled conditions in accordance with EPA, TDEC and OSHA removal and disposal regulations.

4.9 Miscellaneous Mastic Material.

Various types of miscellaneous non-friable asbestos-containing mastic applications were observed during the survey. These applications include weather seals on windows, vapor barriers, roofing mastic, pipe wraps and adhesives. Non-friable mastics applied to friable asbestos-containing substrates such as thermal system insulation has been considered as homogeneous to the friable substrate material.

The non-friable asbestos-containing mastic material, in place and in good condition, is considered a Category I non-regulated ACM by NESHAP definition, and may remain in place during the planned demolition if the mastic is not applied to friable asbestos-containing substrates. The non-friable Category I asbestos-containing mastic material, in its present condition and location, pose a low potential for airborne asbestos fiber exposure.

The removal of non-friable asbestos-containing mastic material should be performed by a qualified asbestos abatement contractor under properly controlled conditions in accordance with EPA, TDEC and OSHA removal and disposal regulations.

4.10 Miscellaneous Debris Material.

Various miscellaneous debris materials were observed in both friable and non-friable forms during our investigation of the designated area. Previous demolition and salvage activities have dispersed building materials such as, brick, concrete, roofing, mastic, adhesives, and in some locations thermal system insulation. Upon further investigation of these materials, the non-friable roofing, mastic and adhesive debris were homogeneous to the roofing, mastic and adhesives from the Power House structure. The thermal system insulation was identified as homogeneous to the Boiler Room thermal system insulation.

Debris fields containing dispersed quantities of known and/or presumed friable asbestos-containing thermal system insulation debris, in place and in poor condition, would be considered as RACM by NESHAP definition. The known and/or presumed friable asbestos-containing thermal system insulation debris, in its present condition and location, pose a high potential for airborne asbestos fiber exposure.

Removal of the known and/or presumed friable asbestos-containing thermal system insulation debris from the boiler room perimeter debris fields must be performed in accordance with the removal operations, waste packaging and disposal of friable asbestos-containing stipulated by NESHAP regulations that include notification, personnel training, no visible emissions and adequately wetting waste materials throughout the process. OSHA regulations consider known and/or presumed friable asbestos-containing thermal system insulation debris removal as Class I removal activities and require the use of engineering controls and other isolation methods that prevent the migration of airborne asbestos from a designated regulated area.

The non-friable asbestos-containing roofing, mastic and adhesive material, in place and in good condition, is considered a Category I non-friable ACM by NESHAP definition, and may remain in place during the planned debris field clean-up operations. The non-friable asbestos-containing debris material, in its present condition and location, pose a low potential for airborne asbestos fiber exposure.

TDEC's interpretation of waste resulting from slicing and other methods that do not cut, grind, sand or abrade Category I non-friable asbestos-containing material is not subject to the NESHAP rule and can be disposed of as non-asbestos waste. OSHA regulations consider asbestos-containing roofing, mastic and adhesive material clean-up operations as Class II removal activities and shall be removed in an intact state with wet removal methods to the extent feasible that prevent the migration of airborne asbestos from a designated regulated area.

The removal of friable asbestos-containing miscellaneous debris material should be performed by a qualified asbestos abatement contractor under properly controlled conditions in accordance with ADEM and OSHA removal and disposal regulations.

5.0 QUALIFICATIONS OF REPORT

A.C.T. Services, LLC., has endeavored to investigate the existing conditions of the Power House and Water Treatment Plant at the Former Liberty Fibers site located in Lowland, Tennessee using generally accepted procedures. Regardless of the thoroughness of our survey, it is possible that some areas concealing asbestos-containing building materials were overlooked or inaccessible.

This report presents general descriptions of various construction materials and the general locations where these materials were encountered. Determination of specific or exact quantities and locations of all hazardous materials within the site was beyond the scope of this work. If questions arise during the planning for demolition or other construction, ACT should be notified to allow our staff the opportunity to review the situation and present recommendations.

Due to magnification limitations inherent in PLM, asbestos fibers in dimensions below the resolution capability of PLM may not be detected. The limit of detection as stated in the method is 1%. The above test results relate only to the items tested and may not be reproduced in any form without the express written approval of EMSL Analytical, Inc. EMSL's liability is limited to the cost of analysis. EMSL has no responsibility for sample collection activities or analytical method limitations. Interpretation and use of test results are the responsibility of the client. Samples received in good condition unless otherwise noted. This report must not be used to claim product endorsement by NVLAP or any agency of the U.S. Government.

Due to magnification limitations inherent in PLM, asbestos fibers in dimensions below the resolution capability of PLM may not be detected. The limit of detection is stated in the method is 1%. The above report relates only to the items tested and may not be reproduced in any form without the express written approval of EMSL Analytical, Inc. EMSL's liability is limited to the cost of analysis. EMSL bears no responsibility for sample collection activities or analytical method limitations. Interpretation and use of test results are the responsibility of the client. Samples received in good condition unless otherwise noted. This report must not be used to claim product endorsement by NVLAP or any agency of the U.S. Government.

Due to magnification limitations inherent in PLM, asbestos fibers in dimensions below the resolution capability of PLM may not be detected. The limit of detection as stated in the method is 100. The above test report relates only to the items tested and may not be reproduced in any form without the express written approval of EMSL Analytical, Inc. EMSL's liability is limited to the cost of analysis. EMSL bears no responsibility for sample collection activities or analytical method limitations. Interpretation and use of test results are the responsibility of the client. Samples received in good condition unless otherwise noted. This report must not be used to claim product endorsement by NVLAP or any agency of the U.S. Government.

Due to magnification limitations inherent in PLM, asbestos fibers in dimensions below the resolution capability of PLM may not be detected. The limit of detection as stated in the method is 1%. The above test report relates only to the items tested and may not be reproduced in any form without the express written approval of EMSL Analytical, Inc. EMSL's liability is limited to the cost of analysis. EMSL bears no responsibility for sample collection activities or analytical method limitations. Interpretation and use of test results are the responsibility of the client. Samples received in good condition unless otherwise noted. This report must not be used to claim product endorsement by NVLAP or any agency of the U.S. Government.
